Case Report

Utero-vaginal prolapse in primigravida: a case report

Seetesh Ghose*, Sunita Samal, Senthil Coumary, Pallavee P, Asha Jenkins

INTRODUCTION

Prolapse is a common complaint of elderly multipara in gynecological practice. There are reports of prolapse occurring in multigravida. But it is a rare event in primigravida. Although a rare occurrence, there is still a need for obstetricians to be aware of the management of uterine prolapse which allows for an uneventful pregnancy, labour and delivery.

CASE REPORT

Mrs. X of 26 years, primigravida, a labourer by occupation with a complain of pain abdomen for one day, attended to the emergency obstetrics outpatient department of Mahatma Gandhi Medical College and Research Institute, Pondicherry, India, on 26th May 2011 at 3.00 PM.

She was married for 2 years. It was a non-consanguineous marriage. She was neither immunized nor had any antenatal visit throughout her pregnancy. Her last menstrual period was on 17th August 2010 and expected date of delivery was on 24th May 2011. Her period of gestation was 40 weeks and 2 days on the date of presentation to the hospital. Her 1st, 2nd and 3rd trimesters were uneventful. There was no significant past history or family history of prolapse.

On examination, her vitals were stable. The uterus was of term size with contractions of 1-2 lasting for 10-20 seconds in 10 minutes. The FHR was 144/BPM. The cervix was visible at the introitus without separating the labia majora. It was partially effaced, soft in consistency, central in positions and internal os was 1.5 cm dilated. The membranes were intact and vertex was at ‘0’ station.

A diagnosis of primigravida at 40 weeks and 2 days period of gestation was POG, with 2nd degree uterovaginal prolapse in latent phase of labour was made. She was observed for spontaneous progression of labour with intermittent monitoring of FHR. After 6 hrs of admission, she entered into active phase of labour and membranes ruptured spontaneously. At that time cervix was 75% effaced but anterior lip was edematous, internal os was 3 cm dilated, vertex was at the perineum and liquor was clear. Inspite of adequate uterine contractions, antiedema measures cervix did not dilate further. So Duhrssen’s incision was given and she delivered a term male baby, 2.1 kg at 2.00 am on 27th May 2011.

ABSTRACT

26 years, primigravida, with second degree of uterine prolapse attended to the emergency obstetrics outpatient department, in latent phase of labour. After 6 hours of admission, she entered into active phase of labour and membranes ruptured spontaneously. In spite of adequate uterine contractions, antiedema measures cervix did not dilate further. Finally, she delivered after giving Duhrssen’s incision.

Her postnatal period was uneventful. Vagina was packed with MgSO4 & glycerine for 7 days. At discharge, uterus was involuted; cervix was at the level of introitus. Patient was advised to review in the OPD after 6 weeks.

DISCUSSION

Pelvic organ prolapse is the downward displacement of structures that are normally located at the level or adjacent to the vaginal vault. Uterine prolapse that occurs during pregnancy is a rare condition. Fewer than 300 cases have been reported in the literature, mostly before the 1970s. Previous estimates have put the incidence of uterine prolapse in pregnancy at 1 in 10000-15000 deliveries worldwide. Incidence in India is 1 in 250. Predisposing factors are atrophy of the supporting tissue at the climacteric, injury sustained during childbirth, congenital or developmental weakness of the supports, chronic cough, constipation, ascites, tumour formation, lifting heavy weights can precipitate the onset of prolapse if weakness is already present. Complications of pregnancy with prolapse are abortion, retention of urine, PROM, chorioamnionitis, early rupture of membranes, cervical dystocia, prolonged labour, obstructed labour, operative interference, sub-involution and uterine sepsis. Management options available are pessary treatment till 18-20 weeks, foot end elevation and antiedema measures like local application of glycerine & acriflavine antenatally. During labour besides bed rest, antiedema measures, prophylactic antibiotics, manual stretching of the cervix and Duhrssens’s incision is given if the head is deeply engaged and cervix remains undilated. Whereas LSCS is done if head is high up. Again in puerperium, ring pessary is applied till involution is complete along with prophylactic antibiotics. A case series of three pregnancies with prolapse by Haywood revealed that all happened in multigravida with history of prolonged labour and instrumental deliveries. Whereas salient features of this case are, it has happened in primigravida without any predisposing factors and outcome was uneventful antenatal period with a term delivery. Probably in our case of prolapse, which was pre-existing, got aggravated during pregnancy.
