ABSTRACT
Background: Discuss relevant laboratory findings raised RDW with age and sex distribution. Establish care guidelines for HIV infected person and altered haematopoeisis resulting in with raised red cell distribution width.
Aims & Objectives: To Review the pathogenesis of the haematological manifestations of human immunodeficiency virus (HIV).
Materials and Methods: Blood was collected in a sterile EDTA containing tube and processed following our established laboratory protocol and by universal precaution as per the guideline of National aids control organization (NACO, India). A complete blood counting including HB%, FCV, Red cell indices, platelet count, Red cell distribution width and total white cell count and differential was done by Automated blood cell counter analyzer of all the patient on antiretroviral therapy. The all cell count indices including WBC count with differential and platelet count, was further confirmed by manual oil immersion smear study method. Peripheral smears study was done with field A and B Stain and Leishman stain.
Results: In our study out of 300 HIV cases 189 cases (63%, n=300) shows increased RDW in which male cases are 125 cases (66.48%, n=188) and female cases are 64 (57.14%, N=112).
Conclusion: RDW is commonly affected haematological parameter in HIV infective cases. Higher red blood cell distribution width is associated with a worse virologic and clinical situation in HIV infected.

Introduction

All peripheral blood cells have been observed in patients with HIV infection with the exception of thrombocytopenia, which can occur in asymptomatic individuals with relatively mild immune deficiency, anaemia¹ and leukopenia are both more frequent and severe in patients with advanced immunodeficiency. Peripheral red blood cells in patients with anaemia are typically normochromic⁰ and normocytic and exhibit a varying degree of anisocytosis and poikilocytosis¹². The perturbation in red cell size and shape is reflected in an increased red cell distribution width.

Macrocytosis is rarely seen. However, in patients receiving therapy with zidovudine, macrocytosis is present in the majority of patients, occasionally with mean corpuscular volumes as high as 120 or greater. Rouleux formation and increased background staining may also be seen; this likely reflects the presence of concomitant hypergammaglobulinemia. As noted previously, schistocytes⁶⁻⁹ and nucleated red cells are present in patients with HIV-associated TTP.

Peripheral blood neutrophils¹² are showed striking dysplastic¹² features, which included detached nuclear fragments, acquired Pelger-Huet anomaly chromatin clumping, neutrophils with strangely shaped nuclei, and a high nucleocytoplasmatic ratio and macropolycytes. The presence of detached nuclear fragments in neutrophils is particularly suggestive. The range of changes seen differ from those that are usual in myelodysplastic syndromes. Hypogranularity is less common whereas bizarrely shaped nuclei and a high nucleocytoplasmic ratio in mature cells are more common, but they are quite uncommon whereas they are characteristic of HIV infection. Typically left-shifted and may exhibit a number of morphologic abnormalities, including enlarged size, hypossegmentation, and Pelger-Huet anomalies¹²,¹⁴. Atypical plasmacytoid lymphocytes are occasionally seen in asymptomatic individuals but are particularly common in lymphopenic patients with AIDS and during acute HIV infection. Large atypical monocytes have also been described with prominent vacuolization and fine nuclear chromatin. Anaemia is the most common haematological abnormality found in children and adult with HIV infection. The etiology of anaemia¹ in adult with HIV infection is multifactorial, and managing anaemia can involve a variety of modalities. HIV infection and its direct effects on HSCs and stromal elements can lead to anaemia. Opportunistic infection and myelosuppressive drugs might also cause anaemia.
**Materials and Methods**

**Study Area and Design:** The present study was conducted at the Department of Pathology MGM Medical College associated with M.Y. Hospital Indore, M.P. The study was designed as an observational hospital based study over a period of time from 2010 to 2012 years.

**Ethical Consideration:** Detailed general, systemic examination along with complete details of patient and informed consent was obtained from all study participant do from ART Center of M.Y. Hospital Indore during the time of registration at center.

**Patients Selection Criteria:** The study targeted medically diagnosed HIV positive cases with the help of ELISA technique and confirmed by western blot under the guideline of National aids control organization (NACO, India) over period of time from 2010 to 2012.

All studied 300 cases registered at ART Center and on HAART between the age of 5 to 69 years who are schedule to visit the hospital at regular intervals of time for routine medical review was studied.

**Laboratory Investigations:** Blood was collected in a sterile EDTA containing tube and processed following our established laboratory protocol and by universal precaution as per the guideline of National aids control organization (NACO, India).

A complete blood counting including HB%, PCV, Red cell indices, platelet count, RDW and total white cell count and differential was done by Automated blood cell counter analyzer of all the patient on antiretroviral therapy. The all cell count indices including WBC count with differential and platelet count, was further confirmed by manual oil immersion smear study method. Peripheral smears study was done with field A and B stain and leishman stain.

**Complete Blood Count (CBC) and Peripheral Smear:**

- **Materials:** Purple vacutainer tube or capillary collector (EDTA), Slides and blue capillary tube, Needle or lancet, Vacutainer holder, Alcohol swab, Cotton balls, Absorbent materials, Slide case
- **Procedure:** Specimen is collected into EDTA (purple vacutainer) (5 or 7ml volume). Blood smears must be made from freshly collected specimen and must be prepared within four hours of collection. A well-made peripheral smear is thick at the frosted end and becomes progressively thinner toward the opposite end. The “zone of morphology” (area of optimal thickness for light microscopic examination) should be at least 2 cm in length. The smear should occupy the central area of the slide and be margin-free at the edges.

**Haematological Examination:** Haematological examination including HB%, PCV, Red cell indices, platelet count and total white cell count with differential count should be done on peripheral smears stained with field A and B stain

**Following Base line investigation were done for all 300 patients:** Haemoglobin in gm/dl (Cyanmethaemoglobin method of automated blood cell counter analyzer) and further confirmation by Sahli’s manual method in case of suspicious readings. RBC counting and RBC indices parameters MCV, MCH, MCHC, PCV & RDW - automated cell counter analyzer RBC morphology study under oil immersion manual stained smear study method. Total and differential leukocyte count - automated cell counter analyzer & confirmed by oil immersion manual stained smear study method, Platelets counts - automated cell counter analyzer & confirmed by oil immersion manual stained smear study method Other counting parameters and morphological changes done under automated cell counter analyzer & confirmed by manual oil immersion smear study method.

**Results**

Out of 300 study cases males (62.66%) are more commonly affected than female (37.34%) [Table - 1]. Out of 300 study cases HIV positive patients are most commonly i.e.44% (n=300) in age group of 31-40 years while least common (1%, n=300) in age of above 60 years [Table 2]. Among male most commonly affected age group is found to be 31-40 years with 41.48% involvement (n=188). Among female also most commonly affected age group is found to be 31-40 (48.21%, n=112). In our study youngest HIV infected male 5 year old boy (our case serial no =11 and art reg. No 225072 and oldest male is 65 year (our case Serial No =292, Art Reg. No. 318651). Our study youngest HIV infected female 5 year old girl (our case serial no =89 and Art reg. No=317521 and oldest female is 69 year (our case serial no =33, art reg. No. = 316130) [Table-3]. Out of the 300 study cases RDW is increased in 189 cases (63.0%, n=300) Male are more commonly affected with125 cases (66.48%, n=188), while female cases are 64 (57.14%, n=112) [Table-4]. Data analysis in increased
RDW with the difference of sex distribution under the Upton’s "N-1" $\chi^2$ value = 2.980, $P = 0.084$ and Pearson’s $\chi^2$ value = 2.998 $P = 0.083$ [Table-5].

**Discussion**

In our study of 300 cases, where 188 (62.66%, n=300) are males while 112 (37.34%, n=300) are females, highest prevalence of haematological manifestation of HIV positive patient i.e. 44% is found between 31-40 years of age. RDW is also commonly affected haematological parameter in HIV positive cases. In our study out of 300 HIV cases 189 cases (63%, n=300) shows increased RDW in which male cases are 125 (66.48%, n=188) and female cases are 64 (57.14%, N=112).

**ACKNOWLEDGEMENT**

I will convey special thanks to my guide Professor Dr. C. V. Kulkarni and co-guide Dr. A. Panchonia to give me an immense support and valuable needy guidance for this work.
