Knowledge, attitude and practice of contraception: a study from rural tertiary health care centre

Beenu Kushwah*, Sonal Agrawal

ABSTRACT

Background: Realizing the ill effects of increasing population, India was the first country to have started a state sponsored Family Planning Programme, long back in 1952; India is the second most populous country of the world only after China. To attain the required targets India needs nationwide surveys to assess the practices of contraception especially in poor performing states in order to utilize the available resources according to local needs.

Methods: Hospital based, cross-sectional survey conducted amongst the women of post natal ward of a referral hospital mainly catering rural population. Knowledge, Attitude and Practice survey of family planning was conducted.

Results: A total of 4221 subjects were interviewed. 58% of these women were aware of contraceptive methods, mostly Permanent followed by IUCD, Condom, least of oral pills.

Conclusions: Spacing methods are less known amongst rural women while the use is even lower which calls for the further strengthening of existing awareness programmes.

Keywords: Contraception, Total fertility rate, Family planning

INTRODUCTION

On First March 2011, Indian’s population stood at 1.21 billion which is projected to be 1.4 billion in 2026.\(^1\) India which accounts for world’s 17.5% population is the second most populous country in the world next only to China (19.4%). Of the 1.21 billion Indians, 68.84% live in rural area while 31.6% live in urban areas, as per the census 2011.\(^1\) Therefore more than half of the total population reside in rural areas in this country.

Despite the fact that India was the first country to start state sponsored Family Planning Programme in 1952, decline in the rate of Total Fertility Rate (TFR) has not been to the extent as was aimed, especially in rural areas. For historical reasons some states in India depicted a tendency of higher growth of population. In order to facilitate the creation of area specific programmes, Government of India in 2001 constituted a group of eight states which were lagging behind in improving their fertility indicators. This group is called as Empowered Action Group (EAG).

Present study was conducted in the state of Madhya Pradesh (MP), one of the members of EAG. Total Fertility Rate (TFR) of MP in 2009 was 3.3, against the national average of 2.6 with even bigger difference between rural and urban areas, rural TFR being 3.6 and urban TFR being 2.3 against the national average of 2.9 and 2 respectively.\(^1\)
One of the main objectives of the family planning programme is to spread the knowledge of contraceptive methods and develop, among the people, an attitude favourable for adoption of contraceptive method. The progress achieved in this sphere is normally assessed from the results of Knowledge, Attitude and Practice survey.²

Present study was conducted amongst the women of post natal ward of one of the tertiary health care centres of MP. Department of Obstetrics and Gynaecology of Gandhi Memorial Hospital had total 4927 deliveries (vaginal and caesarean) during last 6 months period, 90% of these women were from rural areas as there is no other equipped government run health care centre is available across a wide area.

METHODS

This was a Hospital based, cross sectional, observational, descriptive study during a period of 6 months from June to November 2011. After taking informed consents and briefing about the aim of study, a total of 4221 women of post natal ward of our department consented to be interviewed. A 20 point, semi-structured questionnaire was read out to the subjects. Data were collected regarding socio-demographic features, knowledge, attitude and practices of various family planning methods.

RESULTS

Women of age group 18-35 years, were included in the study, 78% belonged to 18-22 years age group. 62% women were illiterate, 24% were literate but without any formal schooling, 11% were literate till primary and rest had studied above primary. Only 3% were employed with regular income, 16% were running some home business, 12% were working as helper’s at others’ houses both with irregular income and 20% were farmers and were helping their husbands (Table 1).

On assessing the knowledge, it was found that 58% of the women were aware of at least one of the available family planning methods, maximum knowledge was for permanent method (Tubectomy-56%, Vasectomy-6%), followed by IUCD (30%), Condoms (28%), and Oral pills (11%) (Figure 1). Although majority (71%) of all women who had knowledge of any family planning methods showed positive attitude towards use but only 6% of these had actually used any method ever, of which majority (53%) had used IUCD, 33% condoms and only 14% had used oral pills resulting in a very high knowledge-practice gap i.e. 96%. None of the participants were aware of emergency contraceptive method (i-pill) (Figure 2, 3).

There was no reliable source of information for majority of participants (72%), while health professionals contributed to only 12% and media to 16%. Only 7% were satisfied with their current method of use (Figure 4).

Main reason for not practicing one of family planning methods were inefficient accessibility to right information and follow up facility if needed (69%), rest were not using any method because of non-cooperation by their husbands and lesser role in decision making.

While majority of participants (67%) were willing to use contraceptive method in future, 9% refused to use any method while 24% were not able to decide. Amongst those who had positive attitude, majority (64%) wanted
to use condom followed by IUCD (28%) and only 8% liked pills.

In our study maximum awareness was for permanent method of family planning and nil for emergency contraception while knowledge for temporary methods in present study was relatively low, which is comparable with another study from India, while it was almost same for all methods in developed regions of world.

**DISCUSSION**

In present study oral pills were used by only 4% women in contrast to the women of the United State where oral pills are the most popular reversible method of contraception. Other study from ICMR also showed low use of oral pills by Indian females, which is comparable to other studies.
The huge knowledge and practice gap of our study has also been observed by others, factors which could be identified for this were; wrong information regarding side effects, scarcity of health care facility to consult if required and lesser role in decision making, all of these are directly related with low literacy levels and inadequate inclusion of the educational sessions related with family planning methods by the health professionals. Findings of study from India observed similar gap because of factors directly related with socio economic development.

A study from Reddy et al. showed relatively low contribution of health care personnel in providing family planning knowledge, which was observed in our study as well. The role of health care personnel in providing contraceptive knowledge should be emphasized as it’s a two way communication process.

Sixty one percentage (61%) women of our study were Para three and above and 46% had underwent unconventional methods for termination of pregnancy at least once before present pregnancy, while 26% had actually wished for termination of present pregnancy but had to continue because of non-availability of the facilities nearby. These findings from our study are an indirect reflection for the need of termination of pregnancy because of poor knowledge and even lesser practice of contraception. According to one study on an average 5 million legal and illegal abortions per annum could be abortion rate of India for current decade. The Indian Survey of Death reports that nearly 18% of maternal deaths result from abortion. Majority of these abortions were illegal and indirectly reflect the significant burden of unmet need of family planning methods available to the women from rural and remote areas.

CONCLUSIONS

In recent years, the need for studies for assessing prevailing contraceptive practices is very important across various regions of this country to know about regional needs. Results of present study clearly reflect an urgent need for facilitating the access to more information, education and communication with the reproductive couples according to individual needs. This study indicates a pressing need for effective intervention strategies, both at the community and clinic level, backed with efficient counselling, motivation and provision of services in Rural and Remote areas.
